# *Ecology and Sustainable Development*

Gevorgyan Suren

Under the increasing level of income and population in the world, the main problem of humanity is the ensuring of sustainable development. Coming from above one question stands: what are the real chances for the reaching to acceptable and sustainable standard of living in the future.

It is obvious the sense of presenting the system of indexes, which are connecting the complex of factors (economical, social, ecological, spiritual, etc.) showing the dynamics of sustainable development of civilization. The following are some of mentioned factors with fixed aspect of the objective reality:

***Economical Aspect:*** The economical activity of civilization must be focused not to the increasing of the consumption of biosphere's natural resources potential but to its rationalization. The economical survive of civilization intends not the growth of materially focused activity volume, but the direction to the intensification its intellectual potential (scientific projects, information systems, etc.).

***Social Aspect:*** The main direction is the analyzing of specificity of relations of global production, which are ensuring the efficiency under the association of market directed and planned economies in local and national views. Accordingly, the solving of cooperation problem of democratic mechanisms and governmental policy directions under the decision making process is available as for regional also for global-national scale.

***Ecological Aspect:*** Making of each decision connected with the technical-anthropological activity intends taking into account of actual and potential socio-ecological consequences.

***Prognostic Aspect:*** The efficiency of decision making is sharply increasing if not only involved short-run and middle-run perspectives, but also estimation of possibility of current processes extrapolation under the long-term period. The conjunction of various level prognoses increases its realization possibility.

***Individual Level:*** The degradation changes of environment are the function of individual. That's why under the basis of realization of sustainable development as in local, also in regional-global level must be available the process of individual's transformation, within the social, cultural and producing activities.

***Local Level:*** Local integration of individuals is implementing within the frames of fixed social, cultural and producing activity. The mentioned activity, in its global mean, brings from the one side to the intensification of degradation changes of human habitat and from the other side - with its purposeful transformation is connected the process of historically structured natural relations stabilization.

***National and Global Level:*** The necessity of adequate permission of "ecology - development" relation contradictions, intend the level of management, which would involve local, national and global touches. It is more and more clear, that the adequate functioning of market directed system in all spheres of activity (also protecting of natural resources) intends not only the comparative

easiness of product, service, resource, etc. exchange, but also the implementing of strict system of planned management under the sphere of cooperation of human-society-biosphere.
